Supplementary Information for Copying is not required for ape cultures Title may change

Alberto Acerbi, William Snyder, Claudio Tennie

Additional model information

This document provides additional information on the individual-based model described in the paper Copying is not required for ape cultures. The tode to run the model and to reproduce the results can be found in https://github.com/albertoacerbi/oranzees, together with a detailed documentation of the model development.

The orangees world

The oranzees model is an individual-based model, fully written in R, that reproduces a world where six populations of "oranzees" (an hypothetical ape species) live. The model is spatially-explicit: the six populations are located at relative positions analogous to the six populations of chimpanzees in Whiten et al. (1999), see Figure 1. For modelling convenience, we put these locations approximately in the centre of a 1000×1000 squared environment in order to be able to process their relative distances, that we use to calculate genetic propensity and ecological availability of the behaviours (see below).

The population sizes are also taken from the real chimpanzees populations considered in the study above. Following Lind and Lindenfors (2010), we use data from R. W. Wrangham (2000):

Group	Population size
Uossob	20
Elabik	42
Ognodub	49
Iat Forest	76
Ebmog	50
Elaham	95

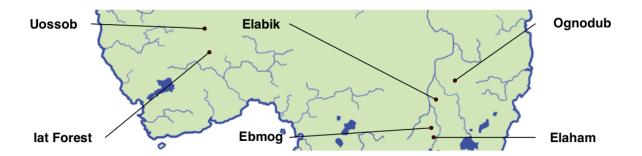

Figure 1: Location of the six populations of orangees.

maybe say sth of the location names here?

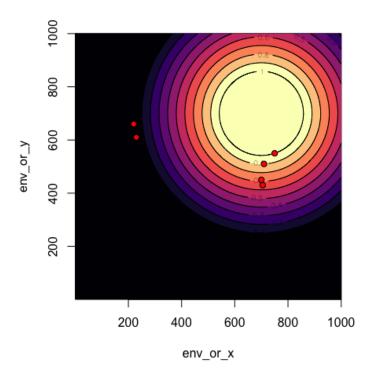

Figure 2: Example of calcualtion of p_g (or p_e). The red points represent the orange populations.

Geographical gradient for genetic propensity and ecological availability

As described in the main manuscript, two parameter of the models, α_g and α_e , determine, independently for each behaviour, the probability that the genetic propensity and ecological availability are equal for all the six populations. Hm, somehow the formulation is not easy for me to understand

say what the point is, i.e. like If they are not equal, the value of p_g (or p_e) are assigned using a geographical gradient, by choosing a random point in the oranzees' world, and calculating its distance to each population. Distances are then transformed to p_g (or p_e) by rescaling them between 0 and 1, so that for the farther population $p_g = 0$ i.e. the associated behaviour will be impossible to express (or $p_e = 0$ i.e. the associated behaviour will be absent with an "ecological explanation") full stop missing

In the example in Figure 2, a particular behavior will have $p_g = 1$ (or $p_e = 1$) in the Ognodub site, $p_g = 0$ (or epicenter $p_e = 0$) in Iat Forest and Uossob, and intermediate values in the other sites.

Sub-categories of behaviours

say why 64 here? There are 64 behaviours, divided in two main categories: "social" and "food-related". Each category is further subdivided in sub-categories. Sub-categories, for food-related behaviour, are further assigned to specific "nutrients". These information are used to calcuatte orangees' state according to its behaviour (see main manuscript). The names of behaviours and of the sub-categories are only suggestive. They are used to illustrate our results in Figure 2 (main manuscript).

Social

Sub-category	Behaviour	
Play	fruit-missile	
Play	slap-fight	
Play	air-split	
Play	leaf-mask	
Play	whistle	
Play	pebble-tease	
Play	tumbling	
Play	brick-fall	
Display	stone drop	
Display	branch pull-release	
Display	arm-cross	
Display	two-hand-drum	
Display	splah	
Display	arm-swing	
Display	explode-leaf	
Display	contorsionist	
Groom	tool back-scratcher	
Groom	hand back-scratcher	
Groom	tongue-bathe	
Groom	tooth-pick	
Groom	dirt-shower	
Groom	ant-shower	
Groom	q-tip	
Groom	exfoliate-fruit	
Courthsip	flower-offer	
Courthsip	hand-stand	
Courthsip	rope-swing	
Courthsip	leaf-fan	
Courthsip	wreath-clutch	
Courthsip	ear-pull	
Courthsip	kissy-hand	
Courthsip	hop-dance	

Food-related

Sub-category	Behaviour	Nutrient
Fruit-hammer foraging	wood-wood	Y
Fruit-hammer foraging	wood-stone	Y
Fruit-hammer foraging	stone-wood	Y
Fruit-hammer foraging	stone-stone	Y
Fruit-hammer foraging	bone-wood	Y
Fruit-hammer foraging	bone-stone	Y
Fruit-hammer foraging	wood-ground	Y

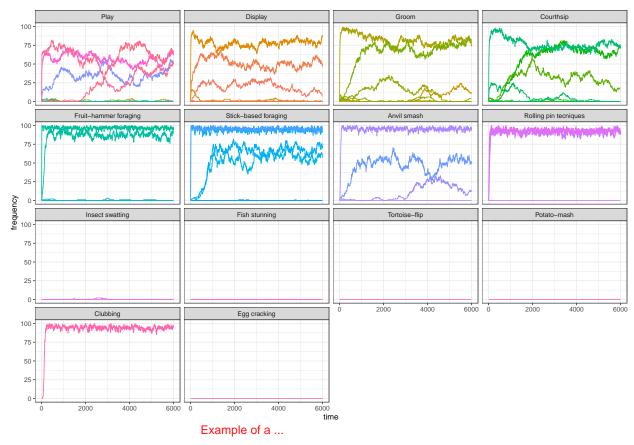

Figure 3: Single run with $\alpha_g = 0.2$, $\alpha_e = 0.8$, and S = 1.

Example of single run

Figure 3 shows an example of the entire history of all behaviors in a single run, for a single population (geographical location and population size are based on "Uossob"), with $\alpha_g = 0.2$, $\alpha_e = 0.8$, and S = 1, i.e. one of the combination of parameters that produces a number of cultural behaviour similar to Whiten et al. (1999).

Age classes to calcualte customary behaviours

To determine *customary* behaviours, we need to define age classes for individuals (the definition of customary behaviours, from Whiten et al. (1999) is a behaviour observed in over 50% of individuals in at least one age class). We define three age classes as follows:

We need a ref here for age classes

We need a ref here for age classes

than

- adults: individuals that are more that 16-year sold.
- subadults: individuals between 8 and 16-year old.
- juveniles: individuals that are less than 8-year old.

Figure S4

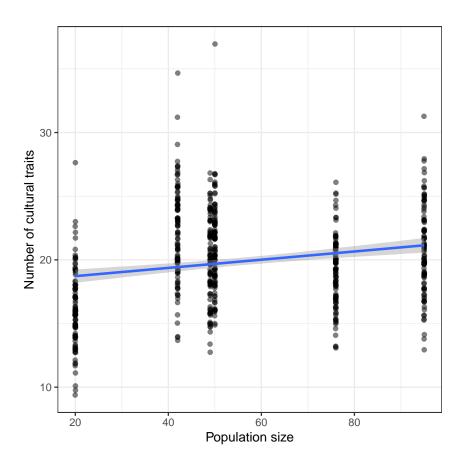

Figure 4: Number of cultural behaviours for each population for the parameters $\alpha_e = 0.8$; $\alpha_g = 0.2$, S = 1. The blue line is a linear fit of the data. N = 100 runs.
